Standard Template Library (STL)

- Standard Template Library (STL) is a powerful library in C++ that provides a collection of **generic data structures** and **algorithms** to simplify common programming tasks.
 - It is based on **templates**.
 - **Goal:** Facilitate development of reusable and efficient codes.
- Key components:
 - **Containers** (+Adapters): Data structures that store objects.
 - **Algorithms:** Predefined functions or operations.
 - **Iterators:** Objects that help traverse elements in the containers.
 - **Functor:** Classes that overload `operator()` to work as functions.

Containers

- Sequence Containers:
 - `vector`, `deque`, `list`, `array`
- Associative Containers:
 - `set`, `map`, `multiset`, `multimap`
- Unordered Containers:
 - `unordered_set`, `unordered_map`
- Container Adapters:
 - `stack`, `queue`, `priority_queue`

Containers

- Sequence Containers:
 - `vector`, `deque`, `list`, `array`
- Associative Containers:
 - `set`, `map`, `multiset`, `multimap`
- Unordered Containers:
 - `unordered_set`, `unordered_map`
- Container Adapters:
 - `stack`, `queue`, `priority_queue`

Due to the matter of time, we will only briefly discuss some of them.

Refer to the official documents for more details.

Sequence Containers:

Elements are stored in an ordered fashion!

vector `(#include<vector>)`

Task	Example: <code>std::vector<int></code>
Create a vector; 8 copies of zero; 5 copies of 3	<pre>vector<int> v; vector<int> v(8); vector<int> v(5, 3);</pre>
Add <code>k</code> to the end of a vector <code>v</code>	<pre>v.push_back(k)</pre>
Remove the last element in a vector <code>v</code>	<pre>v.pop_back();</pre>
Clear the vector	<pre>v.clear();</pre>
Get the element at index <code>i</code>	<pre>w = v.at(i); w = v[i];</pre>

Note:

```
std::vector<int> v = { 9, 7 };  
v[2] = 5; // undefined; out of bound
```

vector (contd.)

Task	Example: <code>std::vector<int></code>
Check if the vector is empty	<code>if (v.empty())</code>
Insert <code>w</code> at some index <code>i</code> of the vector	<code>v.insert(v.begin()+i, k)</code>
Remove the element at index <code>i</code> of the vector	<code>v.erase(v.begin()+i)</code>
Get the sublist in indices <code>[i, j)</code>	<code>vector<int>c(v.begin()+i, v.begin()+j);</code>
Request capacity for a vector	<code>v.reserve(100000);</code>

Note:

`v.begin()` and `v.end()` are iterators (we will introduce them later).

Benefit of `vector<T>.reserve()`

- **Example:** Create a vector of a large number of integers.

```
std::vector<int> v;  
for (size_t i = 0; i < 1000000; ++i) {  
    v.push_back(i);  
}
```

```
std::vector<int> v;  
v.reserve(1000000);  
for (size_t i = 0; i < 1000000; ++i) {  
    v.push_back(i);  
}
```

deque: Similar to vector

(#include<deque>)

- deque (double-ended queue) supports faster insertion anywhere.

```
deque<int> dq{3, 4}; // {3, 4}
dq.push_front(2); // {2, 3, 4}
dq.pop_back(); // {2, 3}
dq[1] = 0; // {2, 0}
```

Note:

deque has `push_front()` and `pop_front()`, while vector doesn't.

Container Adapters

- A wrapper of an (other STL) object that changes **how external users can interact with that object**.
- It modifies or restricts the **interface** of existing sequence containers (`vector`, `deque`, `list`) to provide a **specialized behavior**.
- Examples: `stack`, `qdeque`, `priority_queue`
 - Will be introduced in *Data Structures* course in detail.

Stack

```
(#include<stack>)
```

<https://cplusplus.com/reference/stack/stack/>

- Implementation of LIFO (last-in-first-out) structure.

```
std::stack<T>
```

class template

std::stack

<stack>

```
template <class T, class Container = deque<T>> class stack;
```

LIFO stack

Stacks are a type of container adaptor, specifically designed to operate in a LIFO context (last-in first-out), where elements are inserted and extracted only from one end of the container.

stacks are implemented as **container adaptors**, which are classes that use an encapsulated object of a specific container class as its **underlying container**, providing a specific set of member functions to access its elements. Elements are **pushed/popped** from the **"back"** of the specific container, which is known as the **top** of the stack.

Queue

```
(#include<queue>)
```

<https://cplusplus.com/reference/queue/queue/>

- Implementation of FIFO (first-in-first-out) structure.

```
std::queue<T>
```

class template

`std::queue`

`<queue>`

```
template <class T, class Container = deque<T> > class queue;
```

FIFO queue

queues are a type of container adaptor, specifically designed to operate in a FIFO context (first-in first-out), where elements are inserted into one end of the container and extracted from the other.

queues are implemented as **containers adaptors**, which are classes that use an encapsulated object of a specific container class as its **underlying container**, providing a specific set of member functions to access its elements. Elements are **pushed** into the **"back"** of the specific container and **popped** from its **"front"**.

priority_queue

(#include<queue>)

- Implementation of heap-based priority queue structure.

- Elements are ranked based on a certain priority.

`std::priority_queue<T>`

- It supports constant time lookup at the expense of logarithmic time of insertion and deletion.

priority_queue

https://cplusplus.com/reference/queue/priority_queue/

class template

`std::`**priority_queue**

<queue>

```
template <class T, class Container = vector<T>, class Compare = less<typename Container::value_type> > class priority_queue;
```

Priority queue

Priority queues are a type of container adaptors, specifically designed such that its first element is always the greatest of the elements it contains, according to some **strict weak ordering** criterion.

This context is similar to a **heap**, where elements can be inserted at any moment, and only the **max heap** element can be retrieved (the one at the top in the **priority queue**).

Priority queues are implemented as **container adaptors**, which are classes that use an encapsulated object of a specific container class as its **underlying container**, providing a specific set of member functions to access its elements. Elements are **popped** from the **"back"** of the specific container, which is known as the **top** of the priority queue.

Illustrating Examples

class template

std::stack

```
template <class T, class Container = deque<T> > class stack;
```

```
// Container = std::deque
std::stack<int> stack_deq;
// Container = std::vector
std::stack<int, std::vector<int>> stack_vec;
// Container = std::list
std::stack<int, std::list<int>> stack_list;
```

Associative Containers:

Elements are organized and managed automatically using **keys**!

Elements are stored using a specific ordering mechanism so that it's more efficient for searching, insertion and deletion

map

(#include<map>)

Task	Example: <code>std::map<int, char></code>
Create a map	<code>map<int, char> m;</code>
Add key <code>k</code> with value <code>v</code> into the map	<code>m.insert({k, v});</code> <code>m[k] = v;</code>
Remove key <code>k</code> from the map	<code>m.erase(k);</code>
Check if key <code>k</code> is in the map	<code>if (m.count(k))</code>
Check if the map is empty	<code>if (m.empty())</code>
Retrieve or overwrite value associated with key <code>k</code>	<code>char c = m[k];</code> <code>m[k] = v;</code>

Note: Actually, the underlying type stored in `std::map<K, V>` is
`std::pair<const K, V>`

Comparison operator is required for map (also for set)

```
class Person {  
public:  
    std::string name;  
    int age;  
    Person(std::string n, int a) : name(n), age(a) {}  
};
```

```
std::map<int, int> map1; // OKAY - comparable  
std::map<Person, int> map2; // ERROR - not comparable  
// No operator < defined for Person!
```

Iterators

Have a look at looping over a collection

```
std::vector<int> v{5, 4, 3, 2, 1, 0};
for (size_t i=0; i < v.size(); i++) { // looks good!
    const auto& e = v[i];
    cout << e << endl;
}
// The following way looks great, too.
for (auto &e: v) {
    cout << e << endl;
}
// But how about looping over a set or a map?
// some_element++?? What does ++ mean here?
```

Note: Structured binding is available in C++17, not C++11.

```
std::map<int, char> m;
for (const auto& [key, value]: m) // structure binding here
    // work with key, value ...
```

Iterators

- Iterator can help in iterating over ANY container.
- It becomes more flexible and consistent to traverse and manipulate elements in a container (say `v`).
- The iterator always knows “the next element”.

```
auto it = v.begin();
```

Iterators

- Iterator can help in iterating over ANY container.
- It becomes more flexible and consistent to traverse and manipulate elements in a container (say `v`).
- The iterator always knows “the next element”.

```
auto it = v.begin();
```

Iterators

- Iterator can help in iterating over ANY container.
- It becomes more flexible and consistent to traverse and manipulate elements in a container (say `v`).
- The iterator always knows “the next element”.

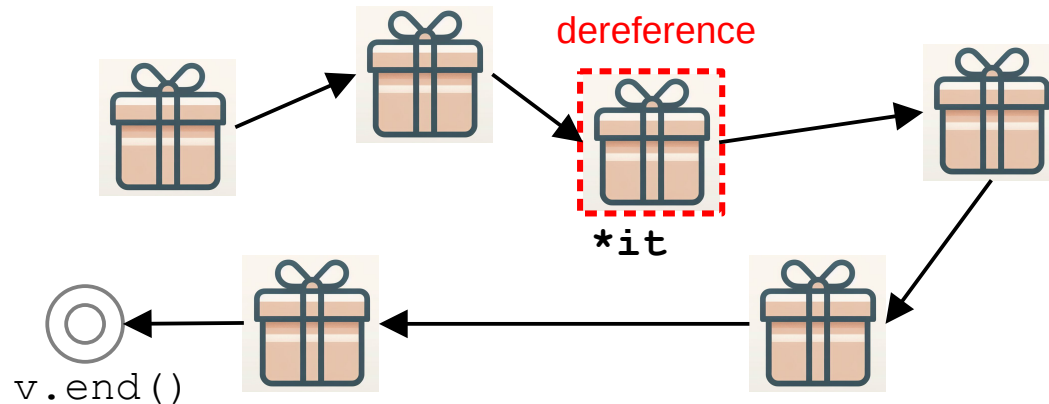

```
auto it = v.begin();
```

Iterators

```

Iterators

- Iterator can help in iterating over ANY container.
- It becomes more flexible and consistent to traverse and manipulate elements in a container (say `v`).
- The iterator always knows “the next element”.

```
auto it = v.begin();
```

Why use `++it` instead of `it++`?

- `++it` increments the iterator first and then returns the updated iterator.
- `it++` returns the current iterator first, and then increments it.
 - An extra step is required here! We have to store a copy of the original iterator!
- However, it still depends on the scenario.

Example: Printing all elements in a map

```
std::map<int, int> map {{1, 6}, {1, 8}, {0, 3}, {3, 9}};  
for (auto iter = map.begin(); iter != map.end(); ++iter) {  
    const auto& [key, value] = *iter; // structured binding!  
    cout << key << ":" << value << endl;  
}
```

```
std::map<int, int> map {{1, 6}, {1, 8}, {0, 3}, {3, 9}};  
for (auto iter = map.begin(); iter != map.end(); ++iter) {  
    const auto& key = (*iter).first; //resolving the issue in C++11  
    const auto& value = (*iter).second;  
    cout << key << ":" << value << endl;  
}
```

Example: 3Sum (LeetCode)

<https://leetcode.com/problems/3sum/>

15. 3Sum

Solved 

Medium Topics Companies Hint

Given an integer array `nums`, return all the triplets `[nums[i], nums[j], nums[k]]` such that `i != j`, `i != k`, and `j != k`, and `nums[i] + nums[j] + nums[k] == 0`.

Notice that the solution set must not contain duplicate triplets.

Example 1:

Input: `nums = [-1,0,1,2,-1,-4]`

Output: `[[-1,-1,2], [-1,0,1]]`

Explanation:

`nums[0] + nums[1] + nums[2] = (-1) + 0 + 1 = 0.`

`nums[1] + nums[2] + nums[4] = 0 + 1 + (-1) = 0.`

`nums[0] + nums[3] + nums[4] = (-1) + 2 + (-1) = 0.`

The distinct triplets are `[-1,0,1]` and `[-1,-1,2]`.

Notice that the order of the output and the order of the triplets does not matter.

Example 2:

Input: `nums = [0,1,1]`

Output: `[]`

Explanation: The only possible triplet does not sum up to 0.

Example 3:

Input: `nums = [0,0,0]`

Output: `[[0,0,0]]`

Explanation: The only possible triplet sums up to 0.

```
</> Code
C++ v Auto
1 class Solution {
2 public:
3     vector<vector<int>> threeSum(vector<int>& nums) {
4
5     }
6 };
```

Example: 3Sum (LeetCode)

- A brute-force solution

```
class Solution {
public:
    vector<vector<int>> threeSum(vector<int>& nums) {
        int len = nums.size();
        if(len==0 || len<3) // at least three elements needed
            return {};
        set<vector<int>> s; // "set" stores unique elements only
                           // duplicate triplets will not be added
        sort(nums.begin(), nums.end());
        // Compare all cases of group of three elements
        for(int i=0; i<len-2; i++){
            for(int j=i+1; j<len-1; j++){
                for(int k=j+1; k<len; k++){
                    if(nums[i]+nums[j]+nums[k]==0){
                        s.insert({nums[i], nums[j], nums[k]});
                    }
                }
            }
        }
        // Insert all unique triplets in result vector
        vector<vector<int>> ans(s.begin(), s.end());
        return ans;
    }
};
```

Example: 3Sum (LeetCode)

<https://leetcode.com/problems/3sum/>

- <https://onlinegdb.com/q5n8kg7ku>

```
#include <iostream>
#include <vector>
#include <algorithm>

using namespace std;
```

- `upper_bound()`:
 - find the **first** element in a sorted range that is **strictly greater** than a given value

```
1  #include <iostream>
2  #include <vector>
3  #include <algorithm>
4
5  using namespace std;
6
7  class Solution {
8  public:
9      vector<vector<int>> threeSum(vector<int>& nums) {
10         //preprocessing
11         int countPos = 0, countNeg = 0, countZero = 0;
12         for (auto it = nums.begin(); it != nums.end(); ++it) {
13             if (*it > 0) {
14                 countPos = 1;
15             } else if (*it < 0) {
16                 countNeg = 1;
17             } else { // *it == 0
18                 countZero++;
19             }
20         }
21         // after preprocessing
22         vector<int>::iterator start, fpos, searchEnd;
23         vector<vector<int>> result = {};
24         if (countPos + countNeg < 2) {
25             if (countZero > 2) return {{0,0,0}};
26             else return {};
27         }
28         sort(nums.begin(), nums.end());
29         for (auto start = nums.begin(); start < nums.end()-2; ++start) {
30             searchEnd = nums.end();
31             if (start > nums.begin() && *start == *(start-1)) continue;
32             for (auto mid = start+1; mid < searchEnd - 1; ++mid) {
33                 if (mid > start+1 && *mid == *(mid-1)) continue;
34                 fpos = upper_bound(mid+1, searchEnd, -(start-1));
35                 if (*fpos-1 == -(start-1) && fpos > mid+1) {
36                     result.push_back({*start, *mid, -(start-1)});
37                     searchEnd = fpos;
38                 } //else searchEnd -= 1;
39                 if (fpos <= mid+1) break;
40             }
41         }
42         return result;
43     }
44 };
```

Example: 3Sum (LeetCode)
